What is PATHFAST[™] Presepsin?

PATHFAST[™] Presepsin is a chemiluminescent enzyme immuno- assay (CLEIA) for the quantitative measurement of the Presepsin concentration in whole blood or plasma.

PATHFAST[™] Presepsin improves the diagnosis and prognosis of sepsis defining its level of severity. It is a valid indicator of risk stratification in septic patients. Due to the fast analysis within 15 minutes and the high prognostic value even at patient's admission, PATHFAST[™] Presepsin is useful in laboratories, emergency- and intensive care units and neonatal departments. An early diagnosis with an excellent prognostic performance and its ability to respond rapidly to the variety of clinical conditions make PATHFAST[™] Presepsin the ideal tool for monitoring treatment, selecting the correct antibiotic-dose or changing it if ineffective.

Presepsin secretion (Fig.1)

sCD14-ST is a 13k Da fragment derived from cleavage of CD14, a glycoprotein of 55k Da anchored to the membrane of monocytes, macrophages and polymorphic neutrophils. CD14 acts as a receptor for lipopolysaccharide (LPS) complexes and the specific LPS binding protein (LBP). It can bind to peptidoglycans and other surface structures present in both Gram- Positive and Gram-Negative bacteria. Once bound to the LPS-LBP complex, it activates the intracellular inflammatory response of the Toll-Like receptor 4 (TLR4)/MD2-complex, trig-gering the host's inflammatory cascade against the infectious pathogenic agent. Phagocytosis and activity of plasma proteases (lysosomal enzymes, cathepsin D) result in the formation of the fragment sCD14 subtype, in particular the 13 kDa fragment of sCD14-ST, known as Presepsin.

Fig. 1: Schematic production of Presepsin

Why choose PATHFAST[™] Presepsin?

Presepsin is a reliable, specific and sensitive biomarker for sepsis and a valuable tool for the very early diagnosis of sepsis by Gram-negative and Gram-positive bacteria or fungi ^[1]. Presepsin rises earlier than other biomarker and does not show unspecific increases ^[2]. Presepsin values help to stratify the severity of the septic disease with excellent correlation to APACHE II-, GCS-, MEDS- and SOFA-score ^[3]. Presepsin exceeds the prognostic power of other sepsis biomarkers and is specifically useful when combined with clinical risk scores like e.g. qSOFA ^[4].

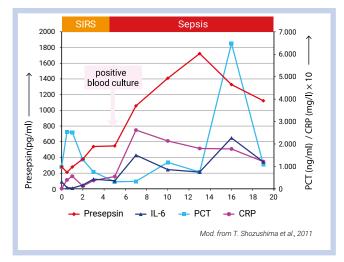

Fig. 2: Clinical course of each septic markers in a burn patient

The time course of Presepsin can be used for monitoring: a decline demonstrates response to therapy and predicts a favorable outcome ^[5,6]. Presepsin is an accurate biomarker in the diagnosis of neonatal sepsis with higher cut off values ^[7,8]. In cardiac surgery elevated preoperative plasma Presepsin concentration is a strong predictor of postoperative mortality in cardiac surgery patients ^[9].

Early marker of sepsis (Fig. 2)

The Presepsin molecule is characterized by rapid kinetics: activation time is only 2 hours following a bacterial or fungal event, with a peak concentration after 3 hours. This characteristic makes the Presepsin molecule the fastest biomarker for sepsis in relation to procalcitonin (PCT) and C-Reactive Protein (CRP), which have activation times of 6-12 hours and 12-24 hours, respectively. The half life of the molecule in plasma is 4-5 hours, compared to 12-24 hours for PCT, allowing more effective and earlier management of the pharmacological treatment.

Presepsin (in red) and other markers in post-traumatic patients follow- ing a serious burn were considered. It is well-known that Presepsin does not change after the trauma but there is an early increase in the values of Presepsin by day 2 following the occurrence of a bacterial infection confirmed by a positive blood culture of day 5. Effectiveness of antibiotic treatment is shown at day 13. Moreover, when patients were divided into an infection group and a non-infection group and ROC curves of each of the markers were plotted to compare Presepsin with other markers, the results showed that Presepsin was the best, followed by CRP, IL-6, and PCT ^[2].

Diagnostic accuracy: sensitivity and specificity

The diagnostic validity of Presepsin has been evaluated in numerous clinical studies. Comparisons of different medical scores and relevant biomarkers in sepsis diagnosis revealed an important role for PATHFAST[™] Presepsin.

Improved 30 day mortality prediction (Fig. 3)

Presepsin showed superior risk of 30 day mortality prediction at admission in septic patients compared to APACHE II, GCS, MEDS, SOFA and procalcitonin.

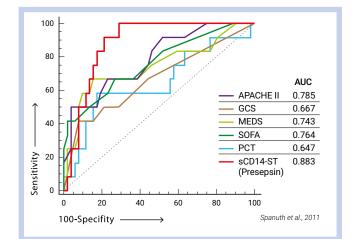

Fig. 3: Comparison of ROC curves for 30 day mortality at admission by Presepsin, PCT and medical scores

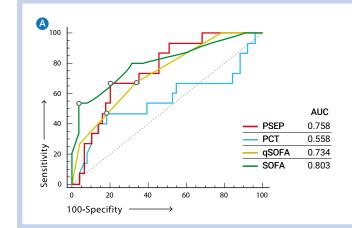

Fig. 4A: ROC curves for 30 day mortality at admission for Presepsin, PCT, SOFA, and qSOFA alone

Support of medical scores (Fig. 4A+B)

Quick-SOFA (qSOFA) was defined by The Third International Consensus Definitions for Sepsis and Septic Shock in 2016 in order to provide a simpli-fied version of SOFA without the need of laboratory tests. It can be directly assessed at patient admission. For discrimination between uncomplicated sepsis and severe sepsis or septic shock Presepsin showed superior dis-criminatory power compared to clinical scores

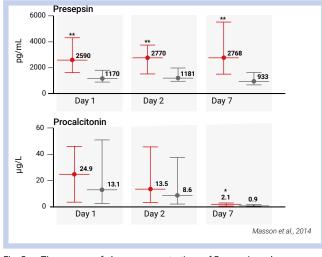

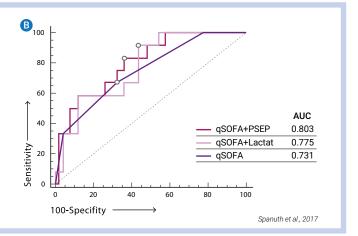

Fig. 5: Time course of plasma concentrations of Presepsin and procalcitonin during ICU stay by survival status. Decedents are shown in red and survivors in black

Presepsin and procalcitonin levels for mortality prediction (Fig. 5) Evolution of Presepsin levels over time in survivors was significantly different from that in deceased patients in the ICU. PCT levels decreased rapidly and similarly in survivors and non-survivors whereas Presepsin clearly differentiates already after 24 hours between the two cases. In comparison to survivors Presepsin levels in non-survivors stayed constantly high over the time period observed. Conversely, PCT levels fell rapidly and similarly from day 1 to 7 in survivors and non-survivors. Presepsin appears as an early marker of mortality with better prognostic performance than PCT and can be used as an aid in risk stratification strategies in septic patients ^[6].

Patients with decreasing levels of Presepsin over 7 days in ICU were more likely to have received an early appropriate first-line empirical antibiotic therapy on day 1 than those with increasing levels ^[5].

and biomarkers. Additionally simultaneous assessment by combining Presepsin and qSOFA improved the diagnostic validity significantly. Combination of Presepsin and qSOFA showed a detection rate for nonsurvivors of 93% and 67% and for patients with severe sepsis/septic shock of 92% and 58% whereas qSOFA alone only reached 67% and 58%, respectively. Presepsin showed also a predictive superiority compared to lactate and procalcitonin ^[4].

Presepsin (pg/ml)	Diagnosis	
< 200	Exclusion of sepsis	
< 300	Systemic infection not probable	
< 500	Systemic infection (sepsis) possible	
< 1000	Significant risk of the systemic infection progression (severe sepsis), increasing risk of unfavorable outcome	
≥ 1000	High risk of the systemic infection progression (severe sepsis/septic shock). High risk for mortality after 30 day comparable with a SOFA score ≥ 8

Fig. 6: Decision thresholds of PSEP for early risk stratification in patients with sepsis

Negative Predictive Value and cut off values (Fig. 6)

An important diagnostic factor is the high Negative Predictive Value (NPV) of Presepsin. In fact for healthy individuals, not affected by a clear bacterial outbreak, the values of Presepsin are below 200 pg/mL. A Presepsin cut off value of 1.622pg/ml excludes 30 day mortality by a Negative Predictive Value (NPV) of 98,5% ^[3]. Presepsin concentration is already related to the severity of the disease at the time of first presentation and may be use-ful in the differential diagnosis in patients presenting with clinical signs of SIRS and sepsis in the emergency department. In summary, based on the Presepsin values measured in the study patients with different disease severity degrees (SIRS, sepsis, severe sepsis or septic shock) and the close relationship between Presepsin and outcome decision thresholds for risk stratification could be established ^[1,10].

Evaluation of Severity

Presepsin correlates significantly with the degree of severity of the infection as its quantitative results increase proportionally. In fact, the studies reveal maximum correlation with the SOFA score values (clinical scoring used most frequently to evaluate organ failure). Higher values on the first day of monitoring are closely associated with a higher incidence of new organ failure and hemodynamic instability in the first 24 hours. All together, Presepsin concentration increased with the SOFA score, the number of prevalent organ dysfunctions or failures, and the incidence of new failures of the respiratory, coagulation, liver, and kidney systems, therefore Presepsin is an early predictor of host response and mortality in septic patients. Changes in concentrations over time seem to reflect the appropriateness of antibiotic therapy^[5].

Time

- > Results in 15 minutes
- > Fast kinetics (2/3 hours after onset of the infectious event) ^[1]
- > Short half-life: 4/5h [11]

Sensitivity

- > Chemiluminescent enzyme
- immunoassay
- > No interference
- > "All-in-one" single use cartridges

Presepsin

Practicality

- > Whole blood or plasma (100 µL)
- > Up to 6 tests in parallel
- > Ideal for Emergency Units

Reliability

> High Negative Predictive Values

COMPACT

- > No unspecific results
- > Excellent correlation
- with medical scores

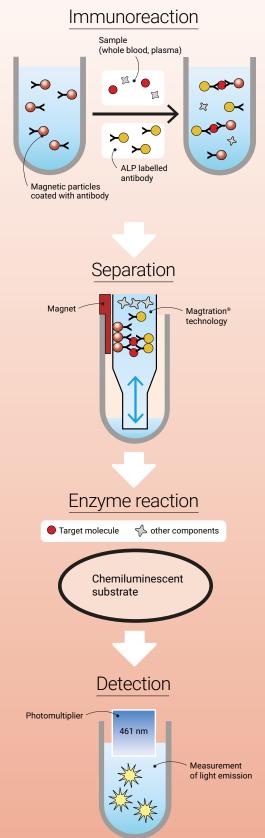

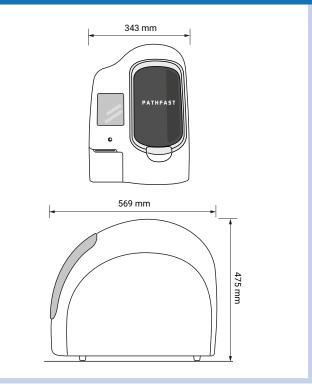

PATHFAST

PATHFAST[™] Test principle

PATHFAST ^{IM} Technical Specifications			
Instrument type	Desktop Immunoassay Analyzer		
Throughput	Up to 6 samples or parameters per run		
Measuring time	<17 minutes for 6 samples using		
	emergency markers or PATHFAST™		
	Presepsin		
Sampling material	Whole blood, plasma, serum		
Measuring principle	Chemiluminescence enzyme		
	immunoassay technology (CLEIA) and		
	Magtration [®] technology.		
Reaction temperature	37 °C		
Sample volume	100 µl		
Data storage	Patient data: 1000, QC data: 1800,		
	CAL data: 300		
Datatransfer	ASTM and Fixed standard		
Weight	28 kg		
El. requirements	100 - 240 V AC (50/60 Hz)		
Power consumption	360 VA		
Monitor/keyboard	LCD touch-screen		
Printer	Integrated		
PC	Integrated, Handheld Barcodereader		
	included		
Interface	RS-232C and Ethernet Port		
Calibration	Factory calibration, 2-point calibration		
	every 4 weeks		
24-h operation (stand-by)	Recommended
